BOTANICAL AND PHARMACOPOEIA DATA

General Information of the Herbal Substance	
Scientific Name	Gloriosa superba L.
Common Name	Glory Lily
Botanical Name	Liliaceae
Country of Origin	India
Cultivated/Wild	Cultivated
Vegetative Stage	Fructification
Harvesting Period	December- March
Part of Plant	Seed
Drying	Natural drying

The herbal substance is not derived from plants listed in CITES Appendix I,II or III.

Colchicine from Indena complies with the current European Pharmacopoeia and it is covered by the following Certificate of European Pharmacopoeia: CEP 2004-182 valid version

PRODUCTION OF ACTIVE INGREDIENT

Indena SpA

Production of Colchicine

Sites:

- **Indena SpA |Settala| Milano|Italy**
  Full process, control and batch release
  or
  Process final steps, control and batch release (in case of importation of the intermediate RAW COLCHICINE)

- **Indena India |Bangalore| Karnataka| India**
  RAW COLCHICINE

Both sites are AIFA and FDA approved

Sommario regolatorio

- **Colchicina Lirca** è stata registrata in Italia con procedura nazionale il **26 aprile 1955** per il trattamento **dell'attacco acuto di gotta e prevenzione dell'artrite gottosa ricorrente**

- Nel marzo **2017** è stata ottenuta l'indicazione " **Trattamento della pericardite acuta e della pericardite ricorrente "** . Acarpia è stata la prima ad ottenere questa indicazione in Europa

- Nel Febbraio **2020** la CTS AIFA ha espresso parere favorevole al rilascio di una nuova indicazione : "**Prevenzione dell'attacco di Febbre Mediterranea Familiare e dell'amiloidosi secondaria a Febbre Mediterranea Familiare nell'adulto e nell'adolescente**"

- Acarpia è fortemente impegnata nella ricerca e sviluppo di nuove indicazioni terapeutiche per la colchicina e numerosi studi clinici sono in corso

Abstract

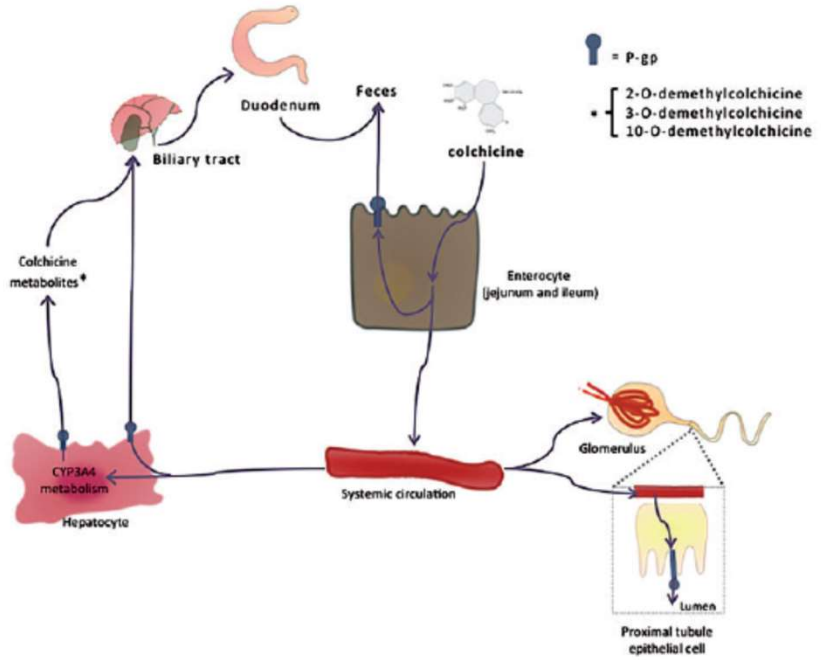
Colchicine is an ancient medication that is currently approved for the treatment of gout and FMF. However, colchicine has a wide range of anti-inflammatory activities, and studies indicate that it may be beneficial in a variety of other conditions. This paper reviews the evidence for the well-established use of colchicine in gout, as well as several other rheumatic diseases. In addition, we highlight the potential benefit of colchicine in cardiac disease, including coronary artery disease in patients both with and without gout.

Key words: colchicine, gout, cardiovascular disease, inflammation

Rheumatology key messages

- Colchicine's mechanisms of action are multiple, and more complex than previously appreciated.
- In rheumatic disease, colchicine is most useful for conditions driven by macrophages and neutrophils.
- Colchicine's anti-inflammatory effects hold promise for prevention/management of cardiovascular conditions, including acute coronary syndromes.

FIG. 1 Major mechanisms of colchicine metabolism and excretion



Colchicine is initially absorbed in the jejunum and ileum. P-Glycoprotein (P-gp) on the apical surface of enterocytes secretes a fraction of unchanged colchicine back into the lumen, from which it can be excreted. The remainder enters the systemic circulation and passes through the kidneys, where unchanged colchicine is excreted through glomerular filtration as well as through direct renal P-gp secretion into the proximal tubule. Within hepatocytes, colchicine undergoes demethylation into three distinct metabolites through the action of CYP3A4. These metabolites, along with a portion of unchanged colchicine, are secreted into the bile via hepatic P-gp, and thence into the duodenum for potential excretion.

Adverse events during oral colchicine use: a systematic review and meta-analysis of randomised controlled trials

Sarah Stewart[1], Kevin Chih Kai Yang[2], Kate Atkins[1], Nicola Dalbeth[1] and Philip C. Robinson[2,3*]

La Colchicina aumenta la frequenza di disturbi gastrointestinali e diarrea, facilmente gestibili con aggiustamento della dose in base alla risposta clinica del paziente; è farmaco generalmente ben tollerato alle dosi terapeutiche consigliate dal medico nel range da 0,5mg fino a 3mg /die previsto nella attuale scheda tecnica e per le indicazioni approvate

Abstract

Background: Colchicine is a widely used drug to treat inflammatory diseases. Due to its long historical use in medicine, controlled clinical trials have been small and there remains some caution with the use of this drug in patients with co-morbidities. The aim of the study is to systematically examine the side effect profile of colchicine in controlled clinical trials across all published indications.

Methods: A systematic review was conducted in accordance with PRISMA methodology. The Cochrane Library, MEDLINE and EMBASE were searched for double-blind controlled trials of oral colchicine in adult patients that reported adverse event data. Meta-analyses were used to determine the relative risk (RR) of adverse events in colchicine users compared to comparator groups.

Results: A total of 4915 studies were initially identified and after exclusions, 35 randomised controlled trials with placebo ($n = 30$) or active comparators ($n = 5$) were included. The most common diseases studied were gout, liver cirrhosis and pericarditis. There were a total of 8659 pooled participants, 4225 participants were randomised to receive colchicine, 3956 to placebo and 411 to an active comparator. Diarrhoea was reported in 17.9% of colchicine users versus 13.1% in comparator groups (RR 2.4, 95% confidence interval (CI) 1.6, 3.7). Any gastrointestinal event was reported in 17.6% of colchicine users and 13.1% of comparators (RR 1.7, 95% CI 1.3, 2.3). Adverse liver events were reported in 1.9% of colchicine users versus 1.1% in the comparator groups (RR 1.6, 95% CI 0.9, 3.0). Muscle events were reported in 4.2% of colchicine users and 3.3% in the comparator groups (RR 1.3, 95% CI 0.8, 1.9). Haematology events were reported in 0.6% of colchicine users and 0.4% of comparator groups (RR 1.34 (0.64, 2.82). No study reported neuropathy events. Other sensory events were reported in 1.1% of colchicine users and 1.5% of comparator groups (RR 1.4, 95% CI 0.3, 6.7). Infectious events were reported in 0.4% of colchicine users and 2.1% of comparator groups (RR 1.0, 95% CI 0.7, 1.5). No study reported death as an adverse event.

Conclusion: Colchicine increases the rate of diarrhoea and gastrointestinal adverse events but does not increase the rate of liver, sensory, muscle, infectious or haematology adverse events or death.

Keywords: Colchicine, Gout, Diarrhoea, Nausea

Review article

The NLRP3 inflammasome and the emerging role of colchicine to inhibit atherosclerosis-associated inflammation

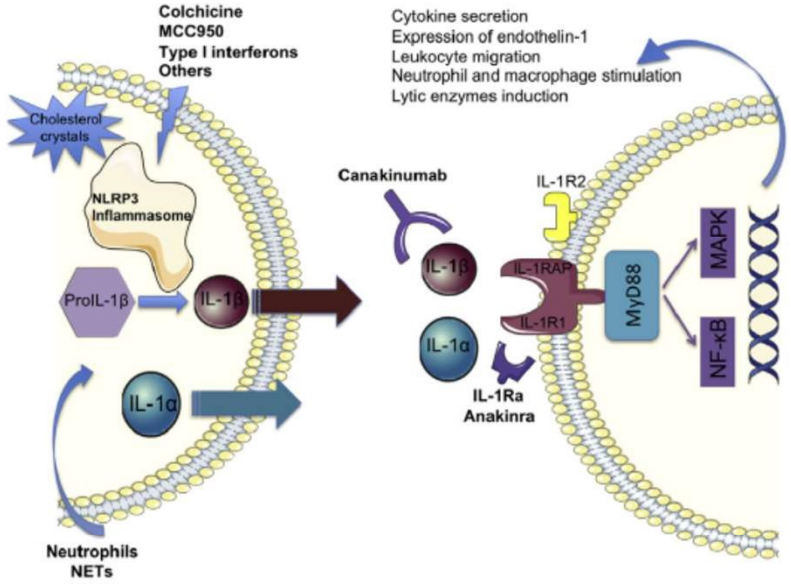

Fig. 1. Interleukin 1α and β activity, natural regulators and inhibitors.
The interleukin 1 is a complex system. While IL-1α acts immediately upon activation, IL-1β requires conversion of its precursor into the active molecule by the NLRP3 inflammasome. Both IL-1α and IL-1β act on the IL-1R1/IL-1RAP complex to activate NF-κB and MAPK signalling. This results in a series of pro-atherogenic effects. These effects can be inhibited by acting on the NLRP3 inflammasome (diminishing IL-1β and IL-18 levels) or by modulating the interaction with the IL-1R1/IL-1RAP complex (i.e. canakinumab, anakinra). IL-1Ra and IL-1R2 are natural regulators of IL-1 activity.

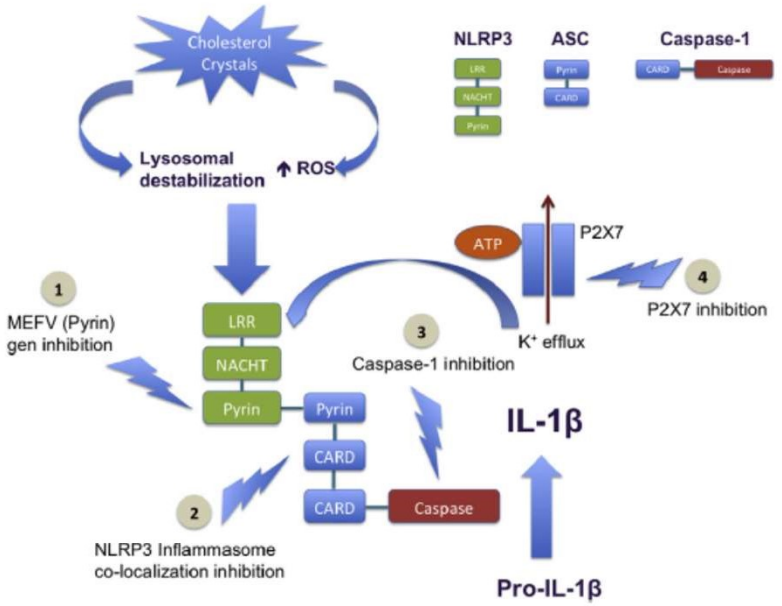

Fig. 2. Colchicine inhibition of the NLRP3 inflammasome.
At least four purported mechanisms of inhibition of the NLRP3 inflammasome by colchicine have been described. 1) Inhibition of MEFV gene resulting in Pyrin (receptor) inhibition; 2) inhibition of inflammasome cytoplasmic co-localization due to tubulin interference; 3) direct caspase-1 blockage; 4) inhibition of P2X7-mediated pore formation resulting in decreased K+ efflux. The final result is inhibition of active form IL-1β (and probably IL-18) production.

Pinto, M.D., Ph.D., Reda Ibrahim, M.D., Habib Gamra, M.D., Ghassan S. Kiwan, M.D., Colin Berry, M.D., Ph.D., José López-Sendón, M.D., Petr Ostadal, M.D., Ph.D., Wolfgang Koenig, M.D., Denis Angoulvant, M.D., Jean C. Grégoire, M.D., Marc-André Lavoie, M.D., Marie-Pierre Dubé, Ph.D., David Rhainds, Ph.D., Mylène Provencher, Ph.D., Lucie Blondeau, M.Sc., Andreas Orfanos, M.B., B.Ch., Philippe L. L'Allier, M.D., Marie-Claude Guertin, Ph.D., and François Roubille, M.D., Ph.D.

RESULTS

A total of 4745 patients were enrolled; 2366 patients were assigned to the colchicine group, and 2379 to the placebo group. Patients were followed for a median of 22.6 months. The primary end point occurred in 5.5% of the patients in the colchicine group, as compared with 7.1% of those in the placebo group (hazard ratio, 0.77; 95% confidence interval [CI], 0.61 to 0.96; P=0.02). The hazard ratios were 0.84 (95% CI, 0.46 to 1.52) for death from cardiovascular causes, 0.83 (95% CI, 0.25 to 2.73) for resuscitated cardiac arrest, 0.91 (95% CI, 0.68 to 1.21) for myocardial infarction, 0.26 (95% CI, 0.10 to 0.70) for stroke, and 0.50 (95% CI, 0.31 to 0.81) for urgent hospitalization for angina leading to coronary revascularization. Diarrhea was reported in 9.7% of the patients in the colchicine group and in 8.9% of those in the placebo group (P=0.35). Pneumonia was reported as a serious adverse event in 0.9% of the patients in the colchicine group and in 0.4% of those in the placebo group (P=0.03).

CONCLUSIONS

Among patients with a recent myocardial infarction, colchicine at a dose of 0.5 mg daily led to a significantly lower risk of ischemic cardiovascular events than placebo. (Funded by the Government of Quebec and others; COLCOT ClinicalTrials.gov number, NCT02551094.)

In prevenzione secondaria post infarto la dose utilizzata è stata 0,5mg /die

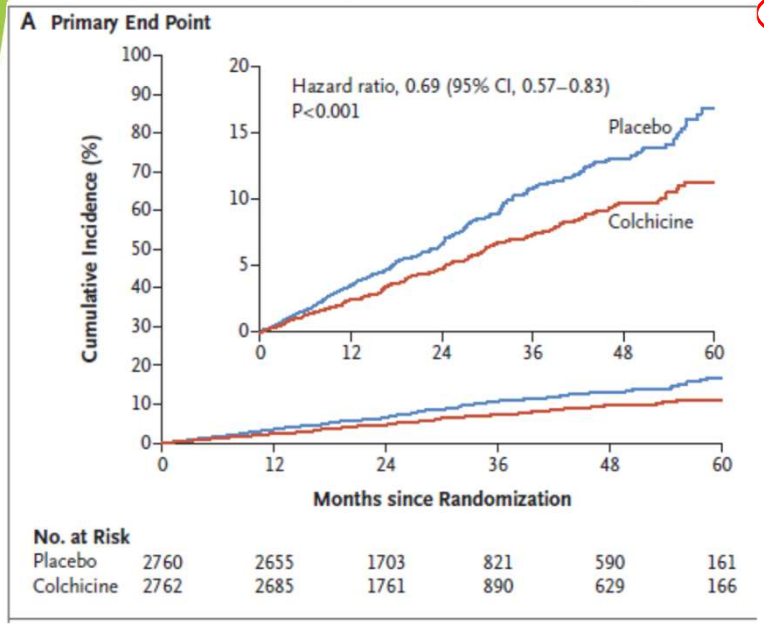
Colchicine in Patients with Chronic Coronary Disease

S.M. Nidorf, A.T.L. Fiolet, A. Mosterd, J.W. Eikelboom, A. Schut, T.S.J. Opstal, S.H.K. The, X.-F. Xu, M.A. Ireland, T. Lenderink, D. Latchem, P. Hoogslag, A. Jerzewski, P. Nierop, A. Whelan, R. Hendriks, H. Swart, J. Schaap, A.F.M. Kuijper, M.W.J. van Hessen, P. Saklani, I. Tan, A.G. Thompson, A. Morton, C. Judkins, W.A. Bax, M. Dirksen, M.M.W. Alings, G.J. Hankey, C.A. Budgeon, J.G.P. Tijssen, J.H. Cornel, and P.L. Thompson, for the LoDoCo2 Trial Investigators*



METHODS

In a randomized, controlled, double-blind trial, we assigned patients with chronic coronary disease to receive 0.5 mg of colchicine once daily or matching placebo. The primary end point was a composite of cardiovascular death, spontaneous (non-procedural) myocardial infarction, ischemic stroke, or ischemia-driven coronary revascularization. The key secondary end point was a composite of cardiovascular death, spontaneous myocardial infarction, or ischemic stroke.

RESULTS

A total of 5522 patients underwent randomization; 2762 were assigned to the colchicine group and 2760 to the placebo group. The median duration of follow-up was 28.6 months. A primary end-point event occurred in 187 patients (6.8%) in the colchicine group and in 264 patients (9.6%) in the placebo group (incidence, 2.5 vs. 3.6 events per 100 person-years; hazard ratio, 0.69; 95% confidence interval [CI], 0.57 to 0.83; P<0.001). A key secondary end-point event occurred in 115 patients (4.2%) in the colchicine group and in 157 patients (5.7%) in the placebo group (incidence, 1.5 vs. 2.1 events per 100 person-years; hazard ratio, 0.72; 95% CI, 0.57 to 0.92; P=0.007). The incidence rates of spontaneous myocardial infarction or ischemia-driven coronary revascularization (composite end point), cardiovascular death or spontaneous myocardial infarction (composite end point), ischemia-driven coronary revascularization, and spontaneous myocardial infarction were also significantly lower with colchicine than with placebo. The incidence of death from noncardiovascular causes was higher in the colchicine group than in the placebo group (incidence, 0.7 vs. 0.5 events per 100 person-years; hazard ratio, 1.51; 95% CI, 0.99 to 2.31).

CONCLUSIONS

In a randomized trial involving patients with chronic coronary disease, the risk of cardiovascular events was significantly lower among those who received 0.5 mg of colchicine once daily than among those who received placebo. Dose utilizzata 0,5mg/die

Diabete/Obesità/sindrome Metabolica - un potenziale meccanismo d'azione utile anche per combattere la Covid19

Abstract

Objective Recent clinical trials have demonstrated that colchicine may have metabolic and cardiovascular and benefits in at-risk patients; however, the mechanisms through which colchicine may improve outcomes are still unclear. We sought to examine colchicine's effects on circulating inflammatory and metabolic molecules in adults with obesity and metabolic syndrome (MetS).

Methods Blood samples were collected pre- and post-intervention during a double-blind randomized controlled trial in which 40 adults with obesity and MetS were randomized to colchicine 0.6 mg or placebo twice-daily for 3 months. Serum samples were analyzed for 1305 circulating factors using the SomaScan Platform. The Benjamini–Hochberg procedure was used to adjust the false discovery rate (FDR) for multiple testing.

Results At baseline, age (48.0 ± 13.8 vs. 44.7 ± 10.3 years) and BMI (39.8 ± 6.4 vs. 41.8 ± 8.2 kg/m^2) were not different between groups. After controlling for the FDR, 34 molecules were significantly changed by colchicine. Colchicine decreased concentrations of multiple inflammatory molecules, including C-reactive protein, interleukin 6, and resistin, in addition to vascular-related proteins (e.g., oxidized low-density lipoprotein receptor, phosphodiesterase 5A). Conversely, relative to placebo, colchicine significantly increased concentrations of eight molecules including secreted factors associated with metabolism and anti-thrombosis.

Conclusions In adults with obesity, colchicine significantly affected concentrations of proteins involved in the innate immune system, endothelial function and atherosclerosis, uncovering new mechanisms behind its cardiometabolic effects. Further research is warranted to investigate whether colchicine's IL-6 suppressive effects may be beneficial in COVID-19.

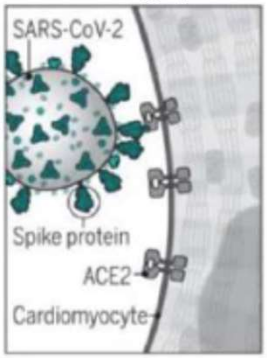
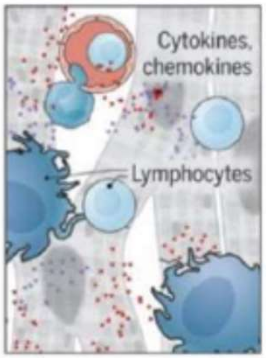
Damaging the heart

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection has the potential to directly and indirectly induce cardiac damage.

GRAPHIC: V. ALTOUNIAN/*SCIENCE*



SARS-CoV-2 can **directly infect** cardiomyocytes, attaching to angiotensin-converting enzyme 2 (ACE2) through its spike protein and entering the cells by fusing viral and cellular membranes.



SARS-CoV-2 infection can **indirectly damage** cardiomyocytes through systemic inflammatory responses and diminished blood supply (e.g., from blood clots and endothelitis, not shown).

Complications

Damaged cardiomyocytes, necrosis, and cardiogenic shock can result from direct and/or indirect effects of SARS-CoV-2 infection. This can lead to scarring and thinning of the myocardium, myocarditis, cardiomyopathy, arrhythmias, and potentially cardiac arrest.

1. SYNOPSIS

Rationale

There is currently no approved treatment available for COVID-19 infection. The use of antiviral drugs Lopinavir, Ritonavir, Darunavir gave It has multiple drug-to-drug interactions with many commonly used drugs in clinical practice; thus, its clinical safety is not determined.

The recommendation for using CLC as treatment of COVID-19 is based on the hypothesis that colchicine controls the cytokine storm occurring during COVID-19 infection by modulating NLRP3 inflamma some activity.

Colchicine (CLC) is an old, low cost and easily available drug with an acceptable known clinical tolerability and safety profiles.

1.2 Objectives and endpoints

Primary	
To evaluate the efficacy of colchicine by describing:	
1. Rate of hospitalization (30 days)	a. Need for hospitalization (at 30 days after randomization)

1.4 Treatment and Duration

Participants in arm 1 will receive current care from day 1 to day 30 plus colchicine 0.5 mg every 8 hours from day 1 to day 7, then colchicine 0.5 mg every 12 hours from day 8 to day 30.
Participants in arm 2 will receive current care from day 1 to day 30.
Colchicine may be lowered at 0.5 mg every 12 hours during the first week or at 0.5 mg every 24 hours during the entire month of treatment in case of gastrointestinal symptom appearance at discretion of the Investigator. Colchicine may cause gastrointestinal side effects, particularly diarrhea, in about 9.6% of patients that usually do not require treatment discontinuation.
The maximum dose is the same approved by EULAR for the treatment of Gout and FMF.
Treatment can be withdrawn in both arms in case of clinical remission (disappearance of symptoms and two consecutive negative swabs at 24 hours) occurring prior of the 30 days after randomization.

CONCLUSIONS AND RELEVANCE In this randomized clinical trial, participants who received colchicine had statistically significantly improved time to clinical deterioration. There were no significant differences in high-sensitivity cardiac troponin or C-reactive protein levels. These findings should be interpreted with caution.

ABSTRACT

Objectives The outbreak of COVID-19 posed the issue of urgently identifying treatment strategies. Colchicine was considered for this purpose based on well-recognised anti-inflammatory effects and potential antiviral properties. In the present study, colchicine was proposed to patients with COVID-19, and its effects compared with 'standard-of-care' (SoC).

Methods In the public hospital of Esine, northern Italy, 140 consecutive inpatients, with virologically and radiographically confirmed COVID-19 admitted in the period 5–19 March 2020, were treated with 'SoC' (hydroxychloroquine and/or intravenous dexamethasone; and/or lopinavir/ritonavir). They were compared with 122 consecutive inpatients, admitted between 19 March and 5 April 2020, treated with colchicine (1 mg/day) and SoC (antiviral drugs were stopped before colchicine, due to potential interaction).

Results Patients treated with colchicine had a better survival rate as compared with SoC at 21 days of follow-up (84.2% (SE=3.3%) *vs* 63.6% (SE=4.1%), p=0.001). Cox proportional hazards regression survival analysis showed that a lower risk of death was independently associated with colchicine treatment (HR=0.151 (95% CI 0.062 to 0.368), p<0.0001), whereas older age, worse PaO2/FiO2, and higher serum levels of ferritin at entry were associated with a higher risk.

Conclusion This proof-of-concept study may support the rationale of use of colchicine for the treatment of COVID-19. Efficacy and safety must be determined in controlled clinical trials.

450 ms. **Results.** Thirty-five patients (18 for Placebo and 17 for Colchicine) completed the study. Both groups were comparable in terms of demographic, clinical and laboratory data at baseline. Median (and interquartile range) time of need for supplemental oxygen was 3.0 (1.5-6.5) days for the Colchicine group and 7.0 (3.0-8.5) days for Placebo group ($p = 0.02$). Median (IQR) time of hospitalization was 6.0 (4.0-8.5) days for the Colchicine group and 8.5 (5.5-11.0) days for Placebo group ($p = 0.03$). At day 2, 53% vs 83% of patients maintained the need for supplemental oxygen, while at day 7 the values were 6% vs 39%, in the Colchicine and Placebo groups, respectively (log rank; $p = 0.01$). Hospitalization was maintained for 53% vs 78% of patients at day 5 and 6% vs 17% at day 10, for the Colchicine and Placebo groups, respectively (log rank; $p = 0.01$). One patient per group needed admission to ICU. No recruited patient died. At day 4, patients of Colchicine group presented significant reduction of serum C-reactive protein compared to baseline ($p < 0.001$). The majority of adverse events were mild and did not lead to patient withdrawal. Diarrhea was more frequent in the Colchicine group ($p = 0.17$). Cardiac adverse events were absent. **Discussion.** The use of colchicine reduced the length of both, supplemental oxygen therapy and hospitalization. Shortly less than half of the patients of the Colchicine group stopped receiving supplemental oxygen until day 2. Clinical improvement was in parallel with a reduction on serum levels of C-reactive protein. The drug was safe and well tolerated. Colchicine may be considered a beneficial and not expensive option for COVID-

NLRP3/ Inflammasome

Alte dosi in cronico come nella FMF sono ben tollerate e sicure

- Pericardite
- Post infarto – prevenzione secondaria

La colchicina ….. Illumina il futuro!

Gloriosa superba

Dosaggi clinici raccomandati per indicazioni terapeutiche le più studiate

Gotta: da 2 a 3 cpr da 1 mg per i primi tre -4 giorni, per una settimana due cpr da 1 mg, poi per 3/4/5 mesi 1 cpr ogni due giorni.
In subacuto 1 o 2 cpr al giorno; come preventivo con dolore e lieve gonfiore da 1 a 2 cpr da 1 mg per uno o due giorni

Pericardite acuta e ricorrente: 0,5mgx2/die pazienti >70kg; 0,5mg una volta al giorno pazienti<70kg; trattamento da 3 a 6 mesi

Febbre Mediterranea Familiare: 1-1,5 mg /die negli adulti fino a max 3mg/die; nei bambini da 0,5 a 1 mg /die in età tra 5 e 10 anni; 1-1,5mg/die nei bambini dai 10 anni

Prevenzione secondaria post infarto : 0,5mg/die per durata di 28 mesi circa studio LoDoCo2

Gloriosa superba

« New friends may be poems but old friends are alphabets. Don’t forget the alphabets because you will need them to read the poems».
W Shakespeare

Nel buio della pandemia a volte siamo spinti a pensare oltre!

Veniamo quindi a noi, il tocilizumab in confronto alla colchicina ha il vantaggio di essere come tutti gli anticorpi monoclonali molto specifico sul bersaglio e quindi ha un profilo di sicurezza potenzialmente migliore, tuttavia interviene bloccando il recettore della IL 6 che è a valle del punto di attacco della colchicina sull’inflammasome (guardi la fig nel paper è molto didattica) che attivato porta al rilascio di IL6.
Quindi sicuramente il tocilizumab è un potentissimo immunosoppressore che blocca l’azione della IL6 e quindi nei processi infiammatori (come la polmonite da COVID 19 che è a tutti gli effetti una sindrome da eccessivo rilascio di IL6) ha una indubbia efficacia, invece la colchicina agendo a monte della cascata che porta al rilascio dell’IL6, se usata in maniera profilattica, ha tutta la potenziale capacità di bloccare il meccanismo che porta al rilascio della IL6 (come avviene nella FMF per intenderci) e quindi potrebbe essere utile anche nel trattamento preventivo della polmonite da COVID 19 in chi manifesta i sintomi inizialòi di questa complicanza che una volta sviluppata sembra rispondere bene al tocilizumab.

GRAZIE PER L'ATTENZIONE
